INTRODUCTION

BACKGROUND

The Florida Department of Environmental Protection (FDEP), along with its partners, is conducting a project to inventory, prioritize, and develop solutions to unpaved roads, which contribute to sedimentation in the Pensacola Bay watershed with the goal of improving water quality. The project includes 1) assessing and identifying unpaved stream crossings contributing the largest sediment loads to the watershed and 2) developing 30% design plans of site-specific solutions at a minimum of 15 priority locations. The 15 locations will be the highest-prioritized sites based on a larger number of sites assessed.

The Pensacola Bay watershed encompasses over 7,000 square miles in northwest Florida and southern Alabama. The Florida portion of the watershed, which is approximately 2,300 square miles, is located within Escambia, Okaloosa, Santa Rosa, and Walton counties. The Pensacola Bay drainage area contains the Escambia, Blackwater, and Yellow River systems and is located within the Choctawhatchee-Escambia Basin (HUC0314). It is composed of eight sub-basins, each defined by an 8-digit Hydraulic Unit Code (HUCs). The Escambia River covers over 4,200 square miles, of which only ten percent is in Florida. The Blackwater River has a drainage area of approximately 860 square miles, with approximately 81 percent in Okaloosa and Santa Rosa counties. The Yellow River has a drainage area of 1,365 square miles, with almost 64 percent located in northwest Florida. Approximately 144 square miles of the Pensacola Bay watershed is considered estuarine.

Cumulatively, the 15 selected projects will help to improve water quality and habitats in the Pensacola Bay watershed by mitigating the effects of unpaved stream crossings contributing the most amount of sediment to the watershed. Unpaved roads cause significant erosion and sediment loading to nearshore water bodies [Programmatic Damage Assessment and Restoration Plan (PDARP)/ Programmatic Environmental Impact Statement (PEIS) Sec. 2-37 5.D.2.2]. While road systems typically occupy a relatively small proportion of the landscape, their construction and maintenance have a great impact on water quality in the adjacent streams and the connected, downstream, aquatic ecosystems (Gucinski, Furniss, Ziemer, & Brookes, 2011), causing loss of habitat and aquatic species decline. It has been well documented that stream-bound sediment interferes with the downstream growth and development of algae, phytoplankton, and submerged aquatic vegetation (SAV) by absorbing or scattering solar radiation necessary for photosynthesis. The 2017 Northwest Florida Water Management District (NFWFMD) Pensacola Bay System Surface Water Improvement and Management (SWIM) plan identifies unpaved roads as one of the challenges in the watershed as they contribute to nonpoint source pollution, turbidity in streams, smothering habitats and impacting water quality and the physical structure of the waterbodies.

OBJECTIVE

As noted above, FDEP and its partners are conducting this project to inventory, prioritize, and develop solutions to mitigate the adverse effects of unpaved roads (with respect to stream sedimentation) in the Pensacola Bay watershed. Task 2 (see task list at right) of the study included collating and reviewing existing inventories of unpaved road stream-crossings, crossovers (i.e., culverts/pipes), and proximity sites. The third task (Task 3) included creation of a geodatabase of sites inventoried in Task 2, focusing on GIS overlays of habitat, protected species localities, road-crossing site conditions, and resource impairments in the watershed. Task 4 encompassed determining the sediment budget of the watershed and contributions of road crossings and to establish sediment reduction goals for crossing sites.

Task 5, which is the subject of this document, describes the process by which the sites in the basin have been prioritized for future field verification, which will then lead to a final ranking of sites to receive roadway and drainage improvements. The intent of roadway and drainage improvements is to reduce sediment runoff for the benefit of fisheries and aquatic species, including those protected by federal and state laws. Therefore, “priority sites” are road stream-crossings that most adversely affect the Pensacola Bay watershed resources and habitats. The prioritization includes a list of individual sites, each with a numeric rank. Sites that were listed as a priority by project partners or scored poorly in the 2011 Yellow River Study and 2009 Eglin Air Force Base Range Road-Stream Crossings Assessment are also included for field verification regardless of the preliminary score assigned by JMT.

This prioritization list will be adjusted prior to compilation of the final priority list (Task 7). Field data from 100 sites (Task 6) and input by project partners will be used to determine the final priority list. The list in this report is therefore considered “preliminary.”

- Task 1: Quality Assurance
- Task 2: Compile and Compare Existing Inventories
- Task 3: Geodatabase / GIS Mapping
- Task 4: Modeling and Sedimentation Reduction Goal Establishment
- Task 5: Preliminary Prioritization**
- Task 6: Field Reconnaissance
- Task 7: Final Prioritization & Habitat and Resource Assessment
- Task 8: Design Plans
- Task 9: Project Management

METHODS

AVAILABLE DATA

Datasets on roads, species, streams, and water quality (compiled for Tasks 2 and 3) were considered for preliminary site prioritization. The following information was considered when prioritizing road-stream crossings for field assessment.

1. Protected species information
 - a. Gulf sturgeon critical habitat
 - b. Endangered Species Act (ESA)-listed mussel critical habitat for
 - i. Round ebonyshell (*Fusconaia rotulata*),
 - ii. Southern kidneyshell (*Ptychobranchus jonesi*),
 - iii. Choctaw bean (*Villosa choctawensis*),
 - iv. Narrow pigtoe (*Fusconaia escambia*),
 - v. Southern sandshell (*Hamiota australis*), and
 - vi. Fuzzy pigtoe (*Pleurobema strodeanum*)

- c. ESA-listed Florida bog frog (*Rana okaloosae*) localities
 - d. ESA-listed Reticulated flatwoods salamander (*Ambystoma bishopi*) critical habitat
 - e. State listed species – grouped by 12-digit HUC
 - i. Blackmouth shiner (*Notropis melanostomus*),
 - ii. Bluenose shiner (*P. welaka*),
 - iii. Saltmarsh topminnow (*Fundulus jenkinsi*), and
 - iv. Florida bog frog (*R. okaloosae*)
2. Water quality information
- a. Waters identified as an “Outstanding Florida Water”
 - b. Streams that are listed by the State of Florida as “impaired,” due to bacteria, nutrients, and/or metals
3. Aquatic barriers
- a. Data from the Southeast Aquatic Resource Partnership (SARP) on which crossings blocked upstream movement of aquatic organisms
4. Sediment erosion analyses
- a. Estimates of annual erosion from each road-stream crossing using the Revised Universal Soil Loss Equation (RUSLE), computed as part of Task 4
 - b. Spatially Referenced Regression On Watershed (SPARROW) data collected as part of Task 4
 - c. Assumptions for weighting the erosion estimates
5. Road surface status
- a. Whether it is currently paved
 - b. If it is scheduled/programmed for upgrade
6. Previous assessments
- a. Project partners indicated road-stream crossings that were a priority for improvement
 - b. The 2011 Yellow River Study, which included an SRI score for all unpaved road-stream crossings in that basin
 - c. The 2009 Eglin Air Force Base Range Road-Stream Crossings Assessment, which ranked all road-stream crossings within Eglin AFB

The nature of each dataset is briefly described below.

Protected Species. Critical habitat designations/maps for gulf sturgeon, mussel species, and reticulated flatwoods salamander were obtained from USFWS websites. The USFWS Panama City field office provided localities for protected mussels and bog frogs. Bluenose shiner, blackmouth shiner, and saltmarsh topminnow watersheds were obtained from Florida Fish and Wildlife Conservation Commission (FWC) websites on each species.

Water Quality. Outstanding Florida Waters (OFWs) were designated by legislation as waters to be protected from degradation from their assigned water quality classification at the time of designation. Impaired waters are those comprising streams/reaches on the Florida’s 303(d) list. Causes for listing vary. GIS polygons were available from FDEP sources for both data sets.

Aquatic Barriers. A database of road/stream crossings and dams that act as barriers to aquatic species movement was retrieved from the SARP website on May 2nd, 2022. It included point-locations and best available data to describe the type of crossing, severity of the barrier, and other site-specific characteristics.

Sediment Erosion Analysis. JMT estimated annual erosion from each road-stream crossing with RUSLE. RUSLE, according to the USDA, predicts long-term, average-annual erosion by water for a broad range of farming, conservation, mining, construction, and forestry uses. JMT calculated an initial RUSLE value (using existing GIS collected data and assumed values) on every unpaved road-stream crossing within the Pensacola Bay Watershed in Florida to estimate the annual sediment load contributed by each crossing and delivered to each corresponding stream. The equation used to compute soil loss, per the USDA Agricultural Handbook 537 (Wischmeier & Smith, 1978), was the following:

$$A = RKLSCP$$

where:

A = soil loss (tons per acre per year)

R = rainfall erosivity (hundreds of foot-ton-inches per acre per hour)

K = soil erodibility factor (ton-acre-hours per hundred foot-ton-per inch)

LS = slope-length and gradient factor

C = crop/vegetation and management factor

P = support practice factor

By applying assumptions about soil type, management inputs, supporting practices, and base management, RUSLE can effectively estimate soil loss for each unpaved road-stream crossing. While two of these variables remained constant (R and P), others (K and C) were assigned an initial value and will be refined through field assessments. The slope-length and gradient factor (LS) was calculated from available LiDAR and topography and averaged along the length of each roadway approach.

Also, watershed modeling work (using SPARROW) shows that some sediment is stored in rivers, floodplains, and reservoirs and is not transported to Pensacola Bay. The delivery fraction, or the percentage of sediment runoff that ultimately is conveyed to Pensacola Bay, was calculated for all catchments. The sediment load calculated for each road-stream crossing was weighted by this delivery fraction. If a road-stream crossing is upstream of a reservoir such that sediment originating from the crossing is stored in the reservoir, then the sediment load from that crossing would be down-weighted which could affect the site ranking.

Road Surface Status. State and county GIS data included shape files for most county roads available for download, while other data were received directly from project partners. From this, the initial data were submitted in Task 3 for review and comment. Project partners provided additional data for roads that were programmed for upgrade or have already been upgraded. Road-stream crossings that have been improved, are either programmed for upgrade, private, or have been decommissioned were eliminated from the list of potential sites for improvement.

DATA SELECTED FOR USE

Ecological Data. All the above listed species were used as criteria to determine preliminary priority rankings. Reticulated flatwoods salamander critical habitat appeared near some unpaved road-stream crossings, so it was considered even though they do not typically inhabit running stream habitat. Some sediment runoff from crossings could deposit on floodplains, potentially impacting habitat for the salamander. Mussels, gulf sturgeon, bluenose shiner, blackmouth shiner, saltmarsh topminnow, and Florida bog frog could each be negatively affected by excessive sediment, so they are all included. The aquatic barrier data set contained

only two currently unpaved road-stream crossings within the watershed. Aquatic barriers from paved roads were not considered, because unpaved roads are the focus of this project.

Water Quality Data. Three water bodies were listed based on nutrient impairment: Pensacola Bay, the inlet to the Bay, and Bear Lake in Santa Rosa County. Sediments from all unpaved road-stream crossings may contribute to nutrient impairment in the Bay, so nutrients were not considered in the preliminary ranking system. Including them would not discriminate between unpaved road-stream crossings. Other waters within the Bay watershed are listed due to metals or bacteria levels. Unpaved road-stream crossings likely do not contribute to metal or fecal coliform impairment, so impaired waters were not used as a criterion for ranking unpaved road-stream crossings. Water bodies listed as an OFW were included in the preliminary ranking system, because excessive sediment could degrade them.

Crossing Characteristics/ Physical Data. Information regarding annual erosion at each unpaved road-stream crossing, calculated for each roadway approach using RUSLE and calibrated with field measurements, was used in the preliminary prioritization. The previously submitted sediment report (Task 4) describes how sediment yield was calculated and calibrated for each unpaved road-stream crossing.

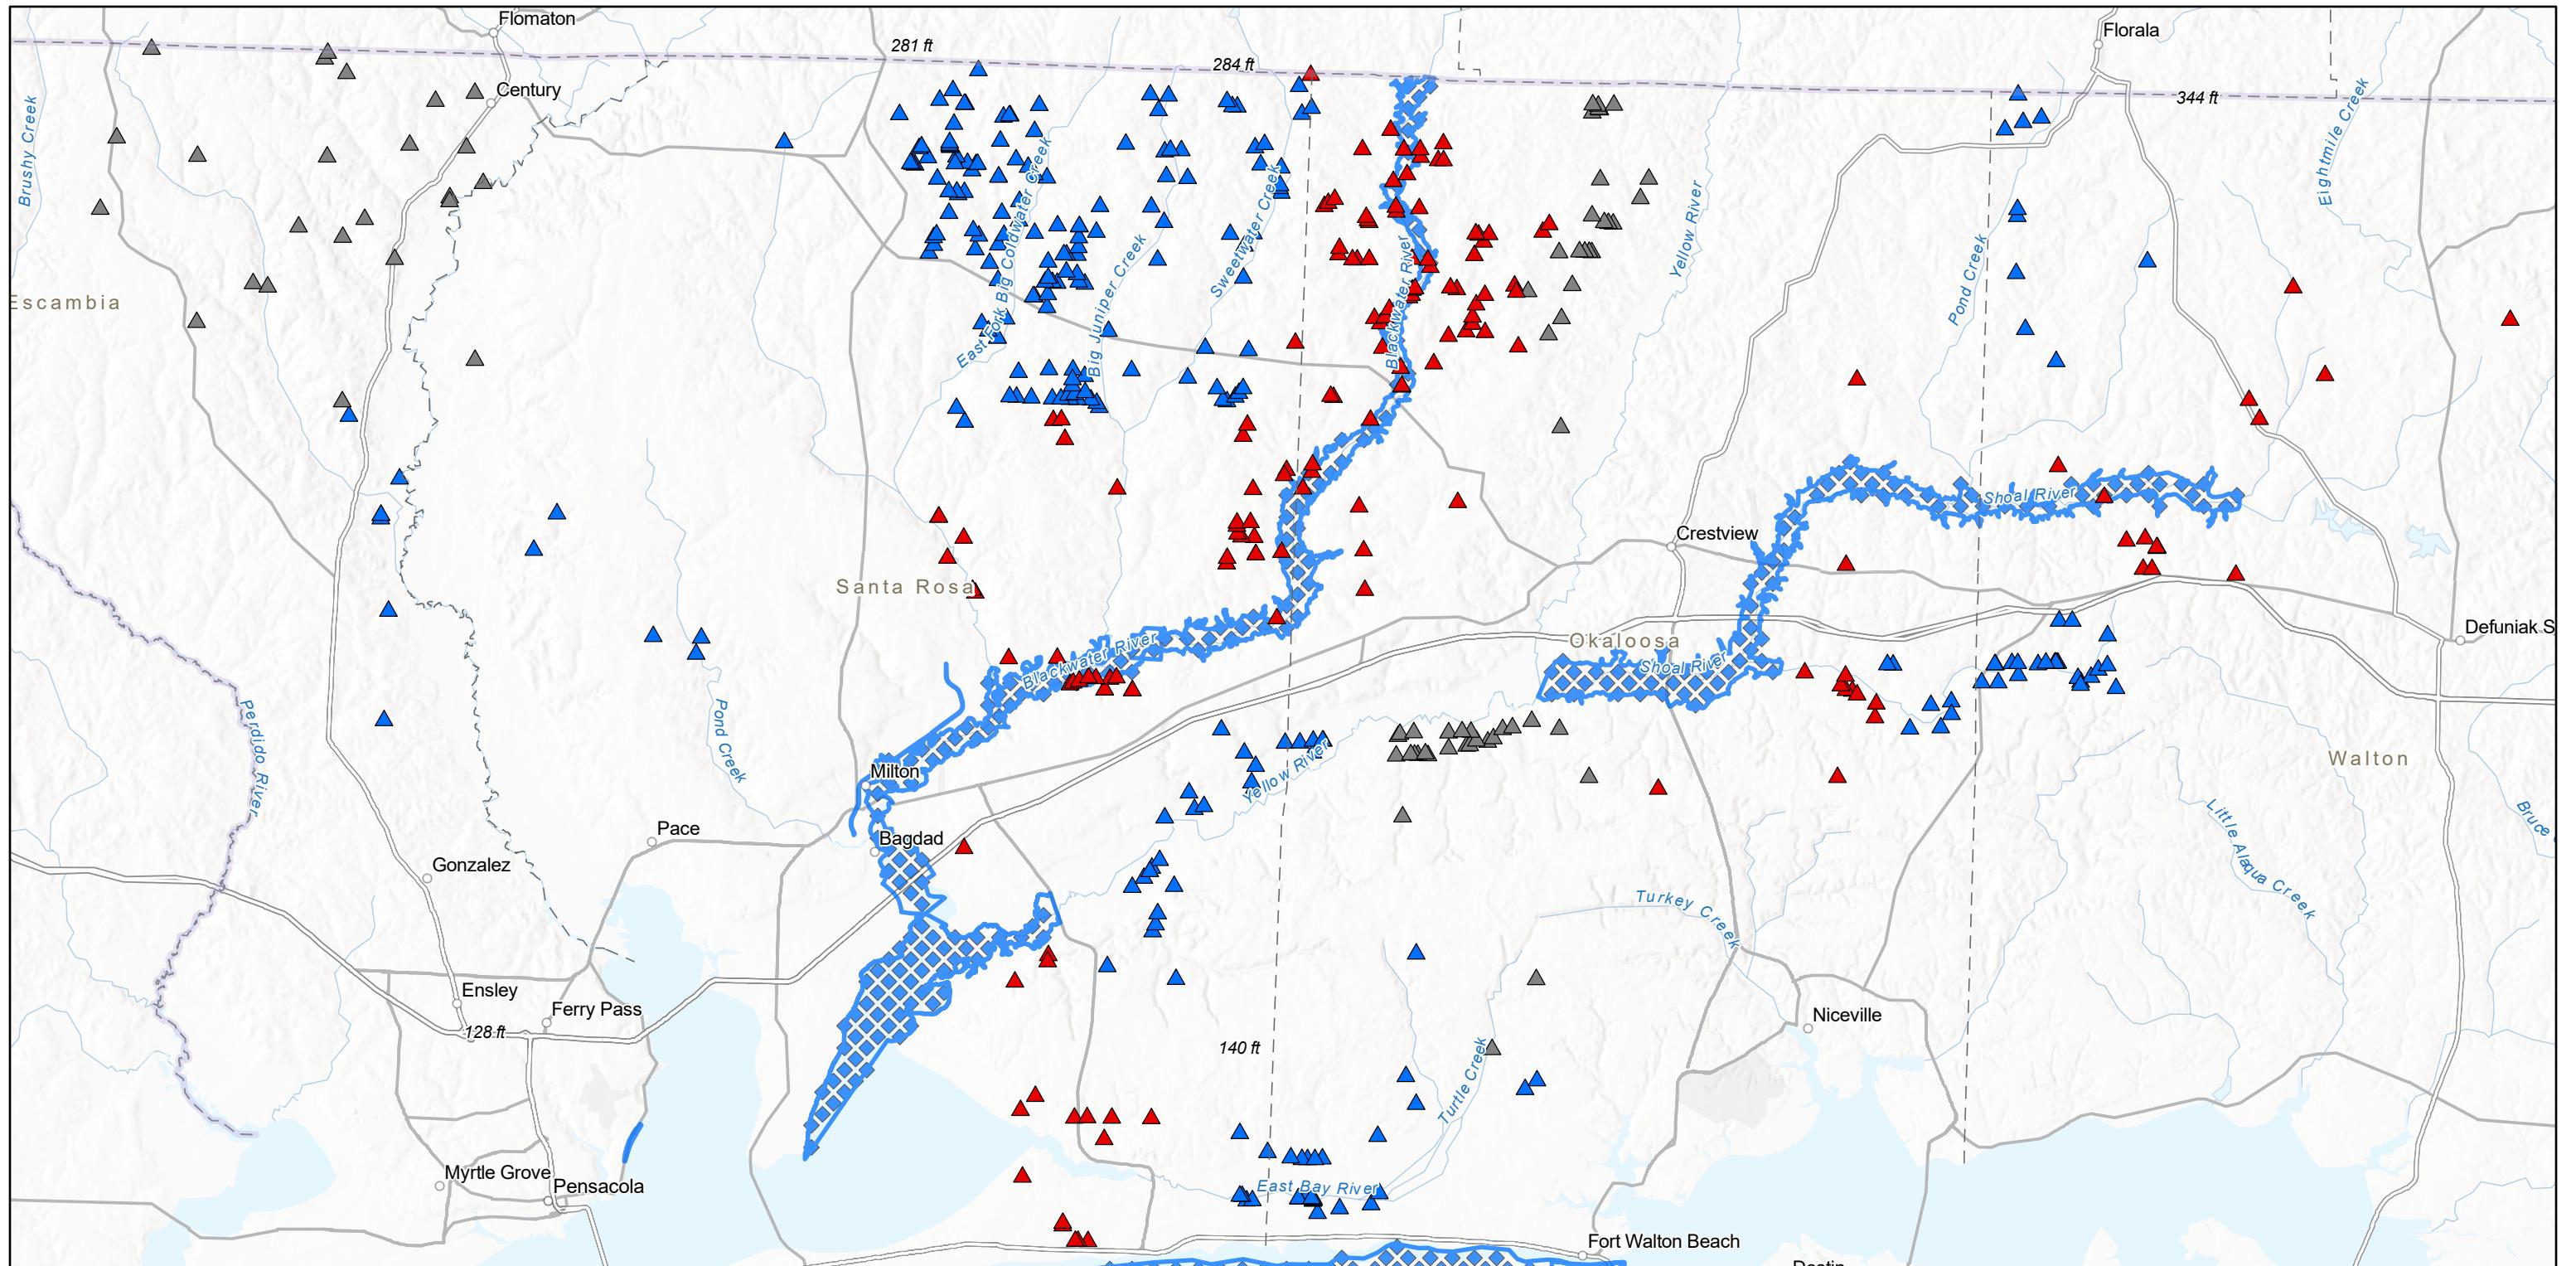

DATA TRANSFORMATION AND ANALYSES

Using OFW, species, and annual erosion data, a scoring system for gauging the relative importance of each parameter was established. Both the species and OFW sub-scores were calculated on a 12-digit HUC basis, i.e., if the site was located inside a 12-digit HUC area having an OFW or a species locality/habitat, the score applied to that site. Those scores were assigned to each unpaved road-stream crossing in the 12-digit HUC, because any improvement in the basin would benefit downstream waters and aquatic species. Estimates of erosion from unpaved road-stream crossings were assigned a numeric score via a natural breaks analysis. The erosion score, OFW score, and species score for each site were added together to provide a final priority score. As part of this process, numeric data for certain parameters were categorized for simplicity.

Outstanding Florida Water Sub-scores

Because unpaved road-stream crossings that are closer to OFWs have a greater likelihood of causing impairment than crossings farther upstream, a system was developed to weight the proximity to the waterbody. If the 12-digit HUC contained an OFW, it was assigned a proximity value of 1. For each upstream HUC, the proximity value would be increased by 1 until reaching the upstream end of the flow path. The OFW score was calculated by dividing 2 by the watershed proximity value. Therefore, watersheds that contain OFWs have a score of 2.0, and upstream watersheds have a score less than 2.0. These scores are depicted in Figure 1.

$$OFW\ SubScore = \frac{2}{Watershed\ Proximity\ Value}$$

Figure 1

Species Sub-Score

For the species sub-score a single point value was assigned for each species type (gulf sturgeon, mussels, bluenose shiner, blackmouth shiner, saltmarsh topminnow, Florida bog frog, and reticulated flatwoods salamander) present in the 12-digit HUC. The value for each site was calculated; the highest possible value was 5 species in a 12-digit HUC even though 7 species or species groups were considered. To maintain a species sub-score with a maximum value of 4, the 12-digit HUC species count was multiplied by 0.8. Scores are mapped in Figure 2. Note that the OFW and species scores overlap in several rivers.

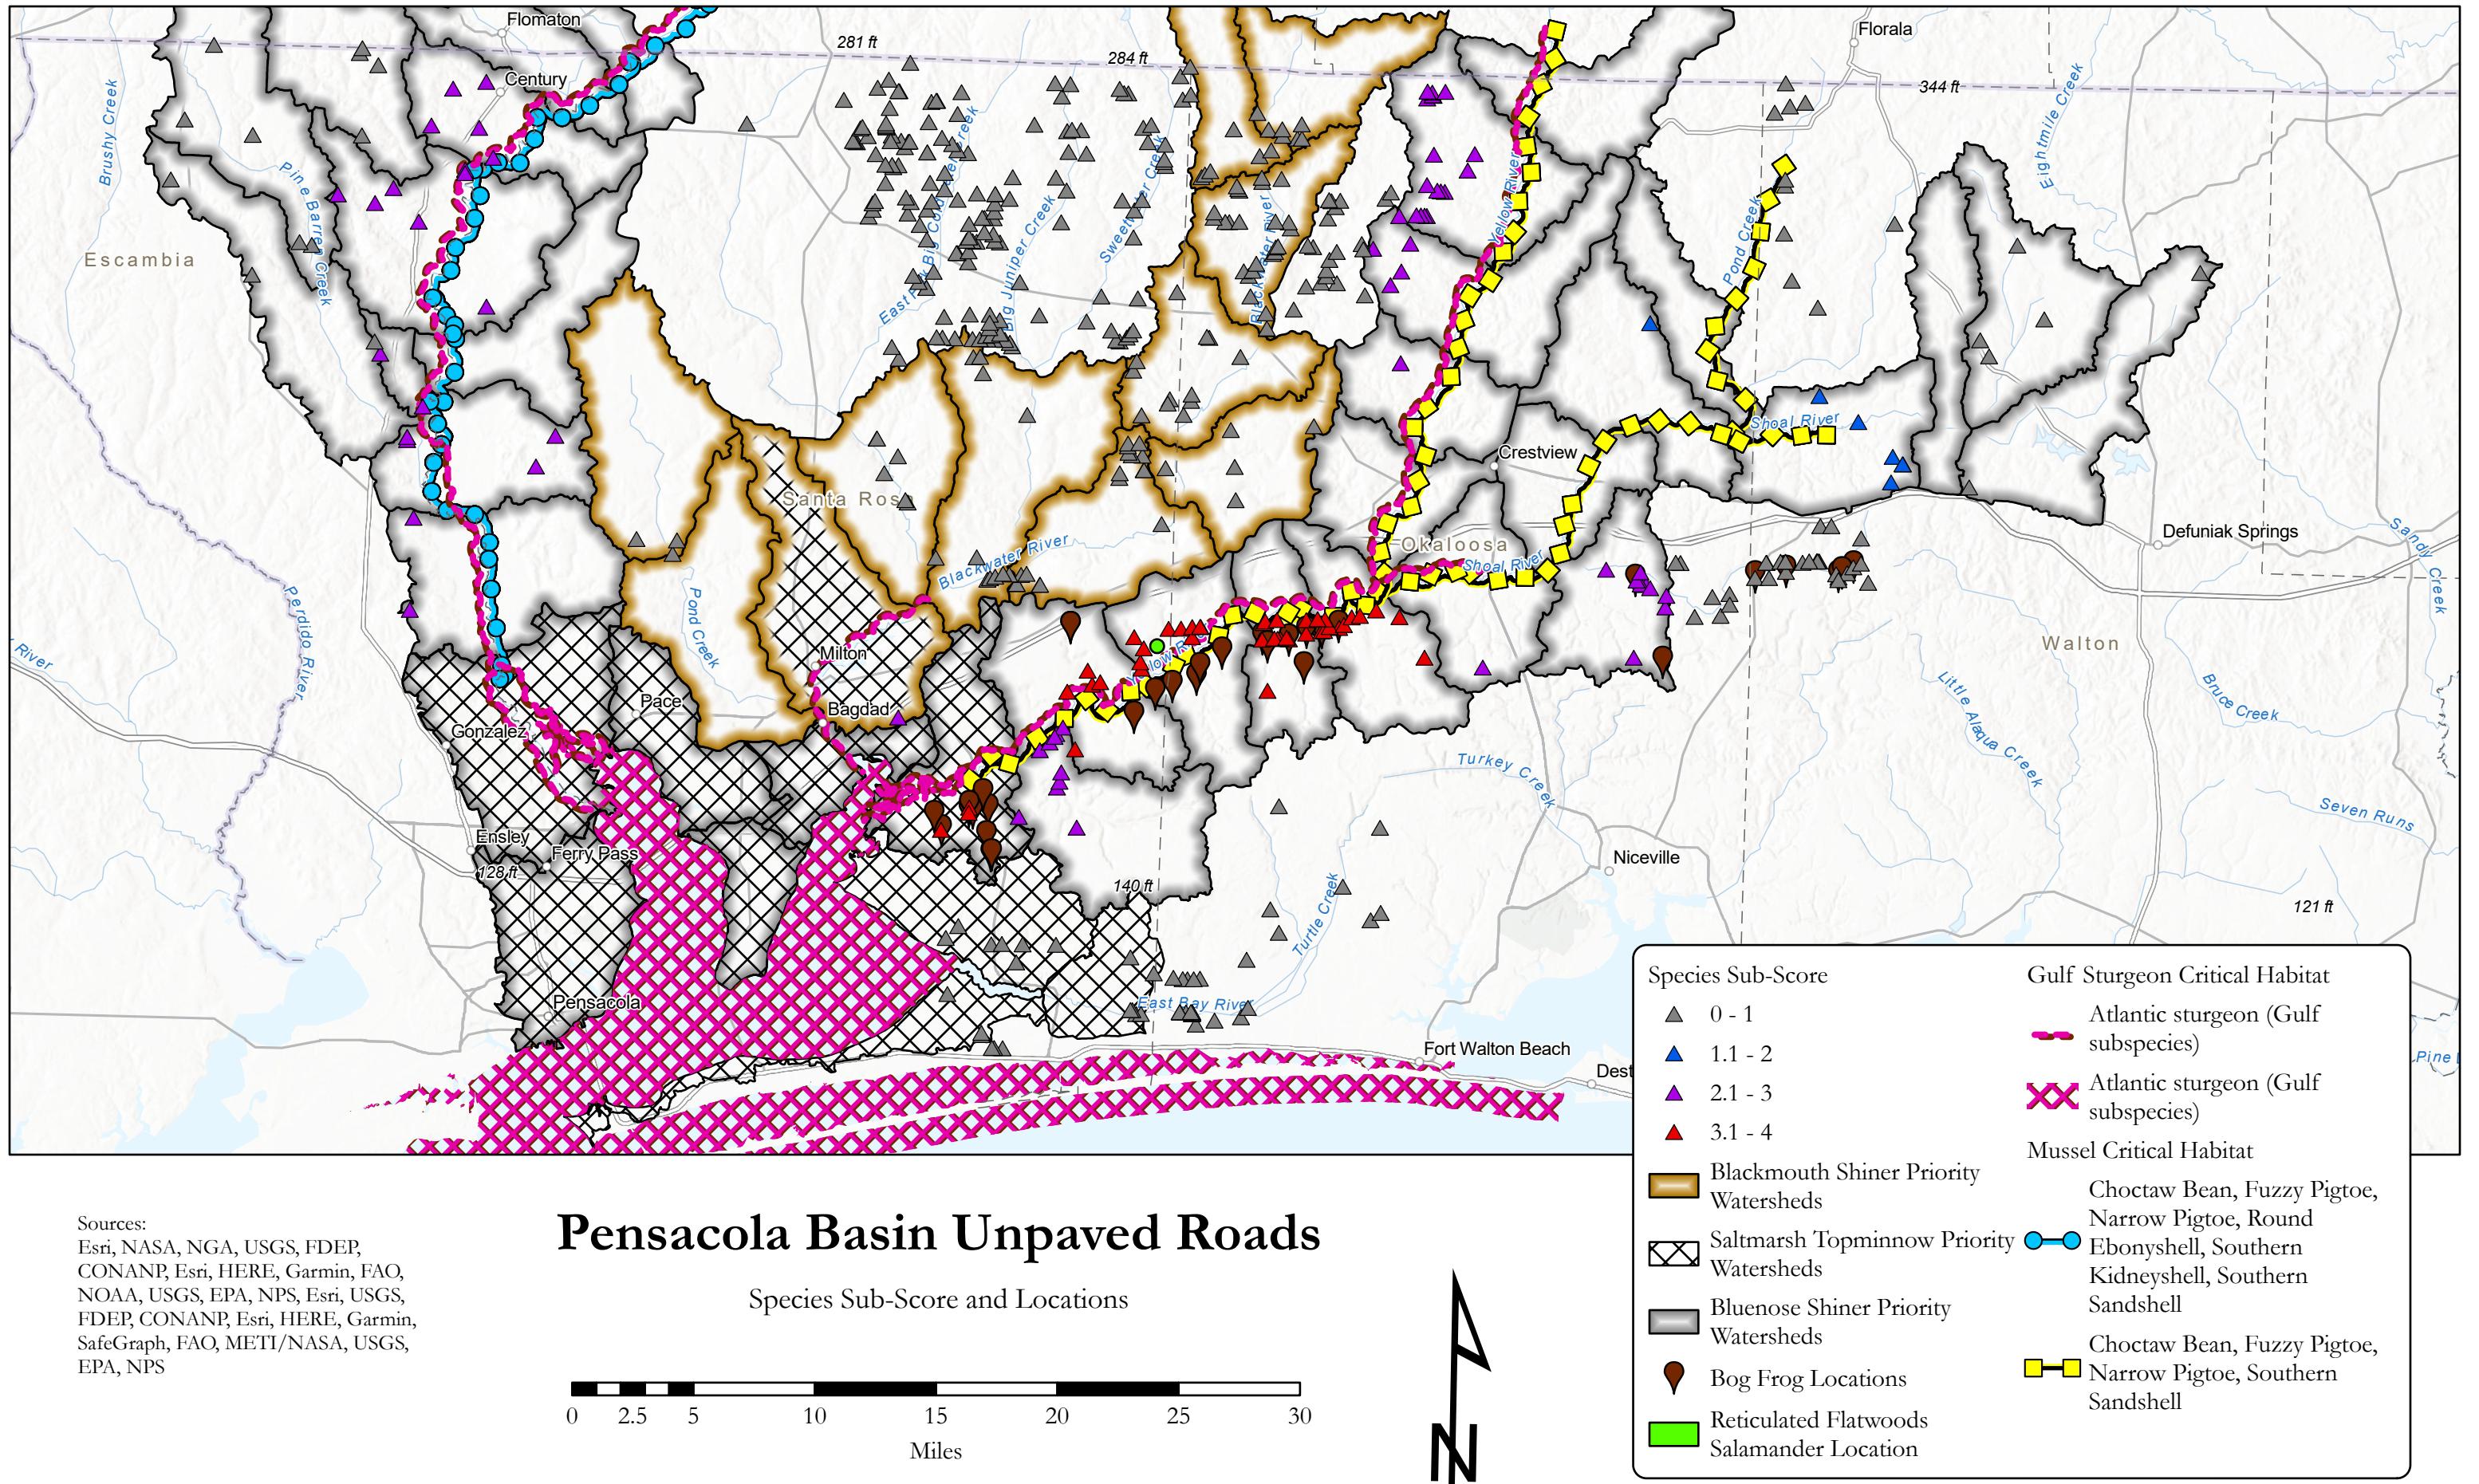

Figure 2

Erosion Sub-scores

The overall objective of the project is to reduce the water quality impact to Pensacola Bay. Not all the estimated sediment will reach the Bay from each unpaved road-stream crossing. Spatially Referenced Regression On Watershed (SPARROW) data collected as part of Task 4 shows that a fraction of suspended sediment originating from each basin is ultimately delivered downstream to Pensacola Bay. Annual erosion estimates from each unpaved road-stream crossing were multiplied by the delivered fraction associated with its catchment. Unpaved road-stream crossings that are more likely to deliver sediment to the Bay are thus given priority.

Additionally, a “use-factor” was applied to each estimate of annual erosion based on preliminary visual observations made in the field. It is assumed that unpaved roads with regular traffic are continually disturbed and are more likely to erode than a road with limited traffic. For example, some State Forest roads have vegetation growing on them which helps reduce erosion. Less routine grading also leaves fewer berms made from unconsolidated sediment on the roadsides compared to roads that are graded routinely. Conversely, many county roads with daily residential traffic display signs of constant grading, rutting, and a pattern of sediment actively filling roadside ditches. Preliminary observations at Eglin AFB indicate a mix of heavy and minimal use roads. County roads, state forest roads, and Eglin AFB roads were assigned use-factors (multiplier) of 1.0, 0.6, and 0.7 respectively.

$$\text{Adjusted Erosion} = \text{Annual Erosion Estimate} * \text{Delivery Fraction} * \text{Use Factor}$$

After adjusting annual erosion estimates based on delivered fraction and use-factor, the estimates were categorized into ten classes using a natural breaks analysis. The classes are listed in Table 1. The erosion sub-scores are mapped in Figure 3. Note that some unpaved road-stream crossings are near other unpaved road-stream crossings on the same road, such as unpaved road-stream crossings on adjacent tributaries at the bottom of a wide floodplain. JMT added the estimates of annual erosion from the roadway approaches together. However, this exercise did not change the score for any of these unpaved road-stream crossings if they were considered jointly, so the results are not included.

Table 1: Unpaved Road-stream Crossing Annual Erosion Sub-Score Categories

Annual Erosion at Unpaved Road-stream Crossing (tons/year)	Category Value
0 – 3.2	1
3.3 – 7.3	2
7.4 – 12.3	3
12.4 – 19.1	4
19.2 – 27.9	5
28.0 – 38.3	6
38.4 – 53.2	7
53.3 – 83.8	8
83.9 – 153.5	9
153.6 – 302.1	10

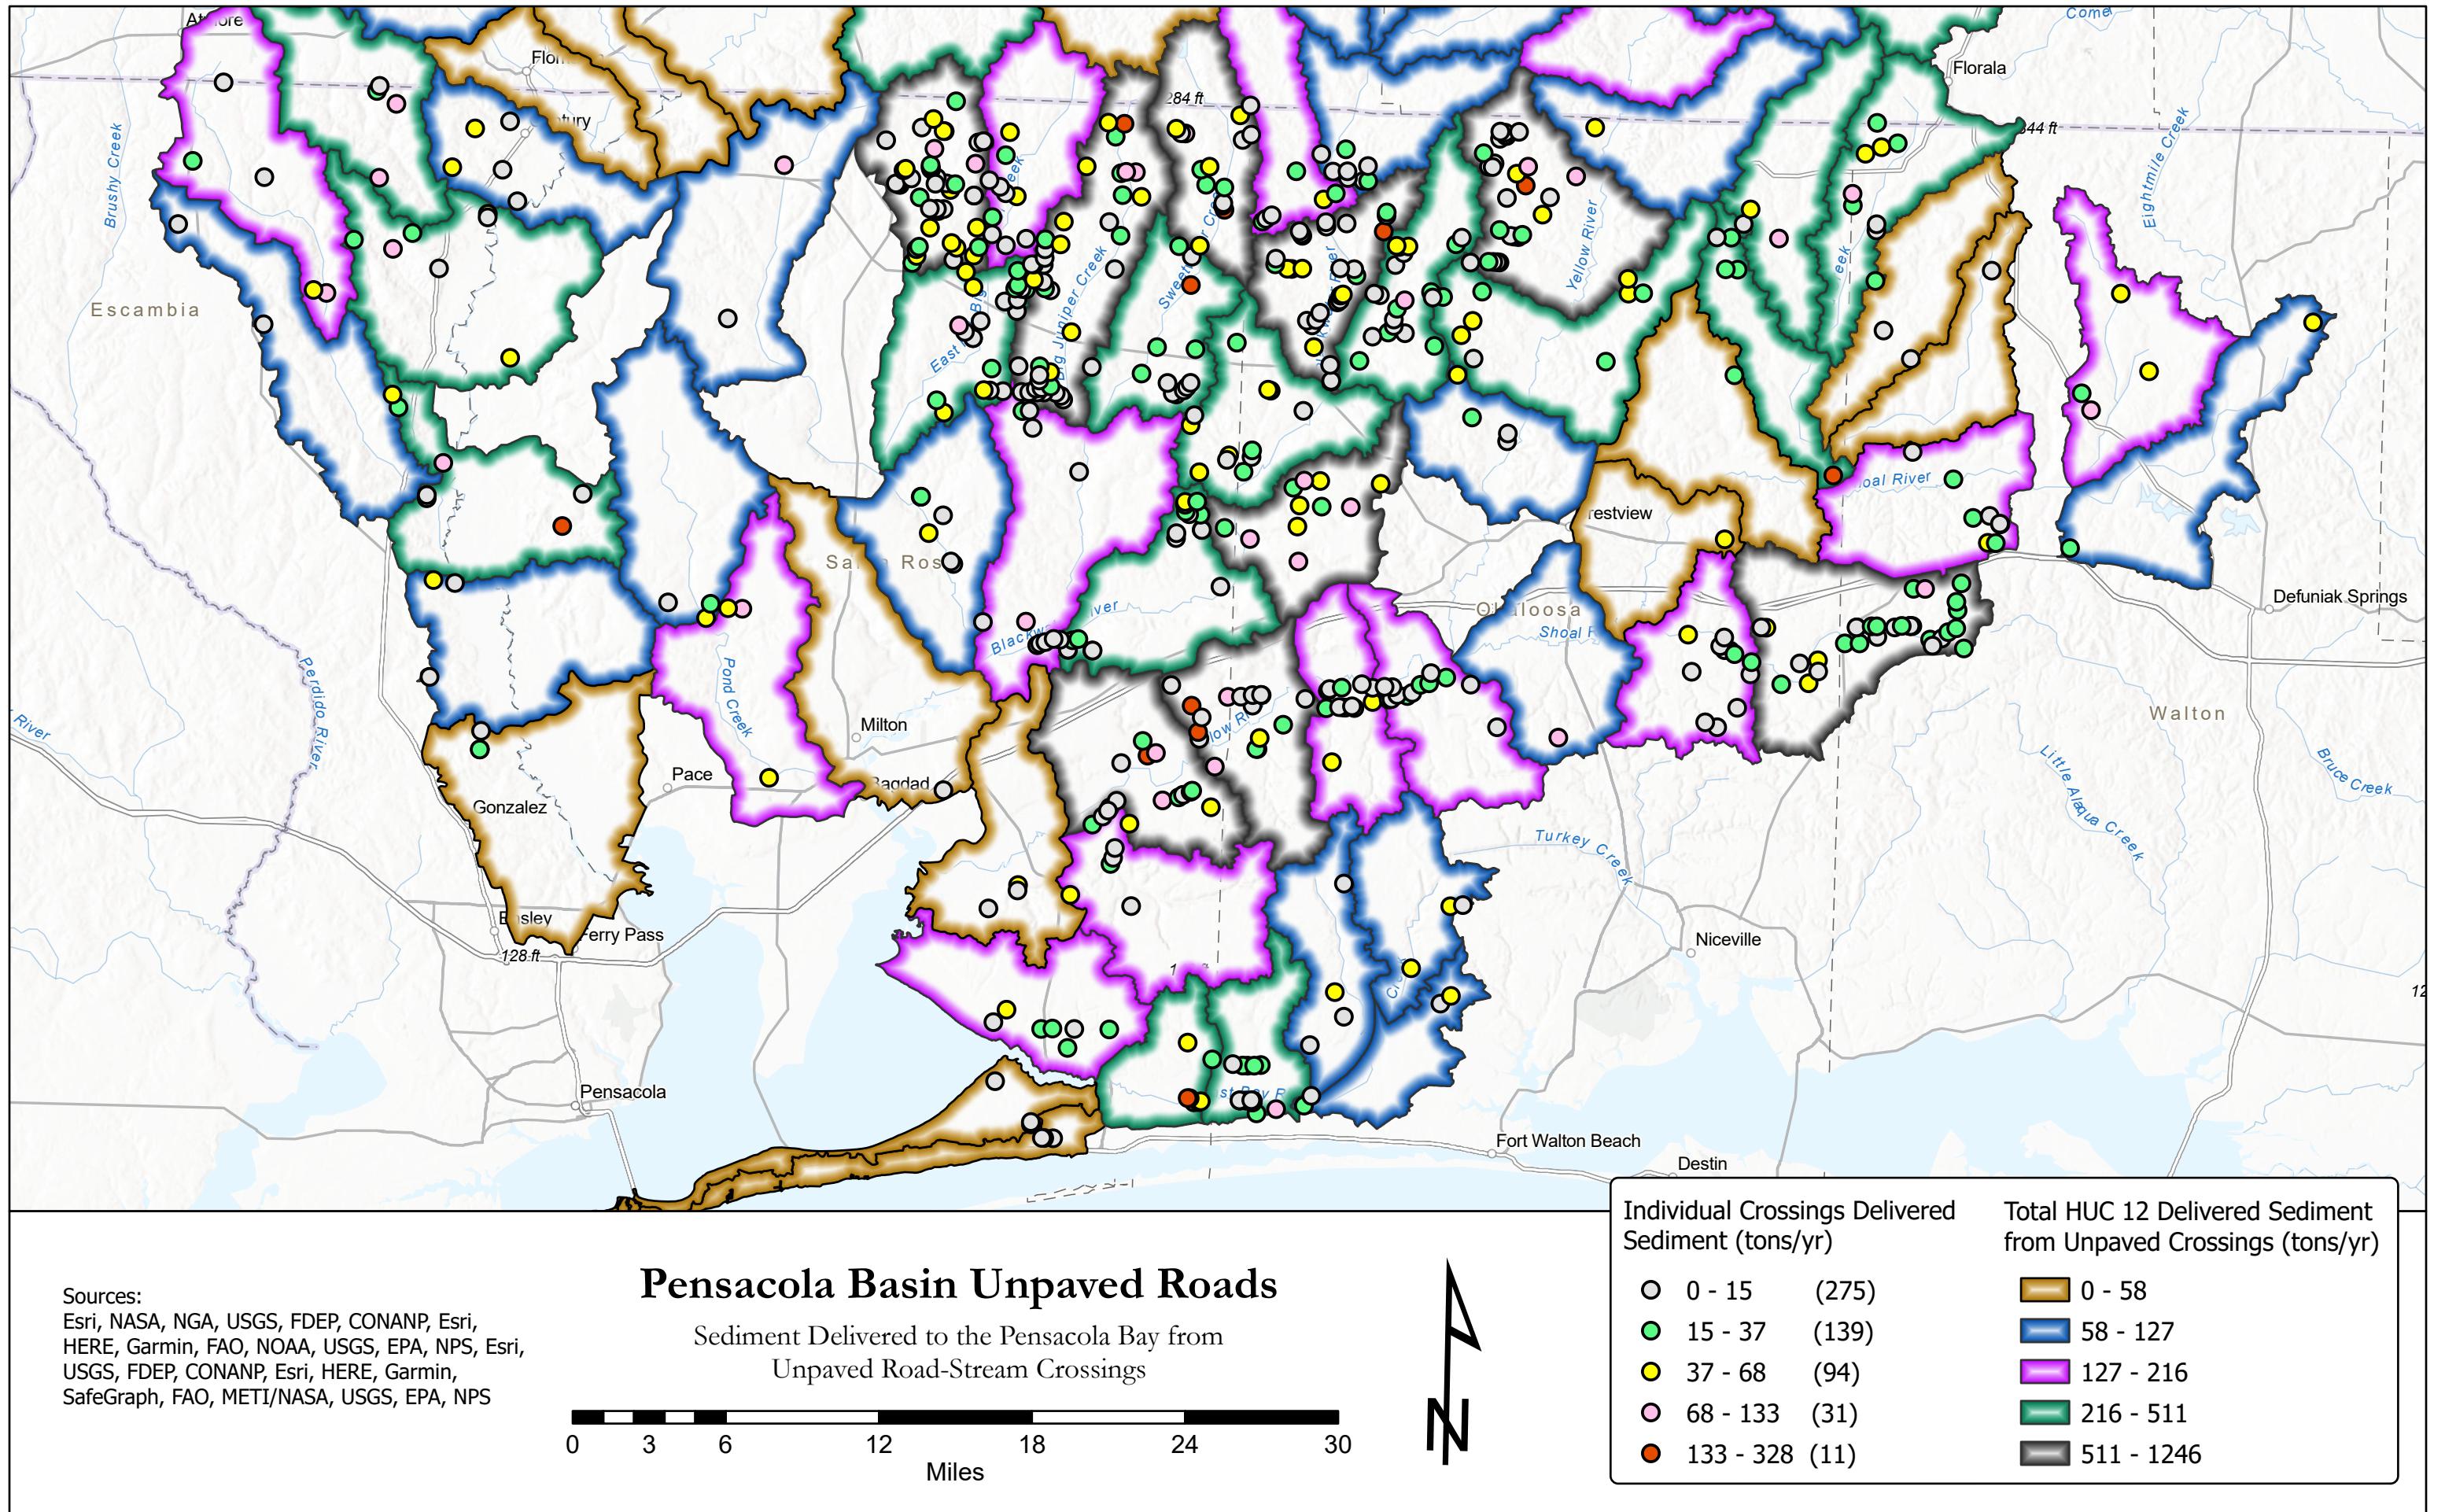

Figure 3

Prioritization Total Score

The prioritization total score is the sum of the three sub-scores (OFW, species, annual erosion). The project objective is to reduce sediment impacts to Pensacola Bay. Therefore, the schema below (Table 2) gives greatest weight to the annual erosion score. Roadway and drainage improvements to crossings with high annual erosion scores would have a positive impact on nearby aquatic species and downstream OFWs. The scores increase with the priority for restoration; a maximum score of 16 is possible.

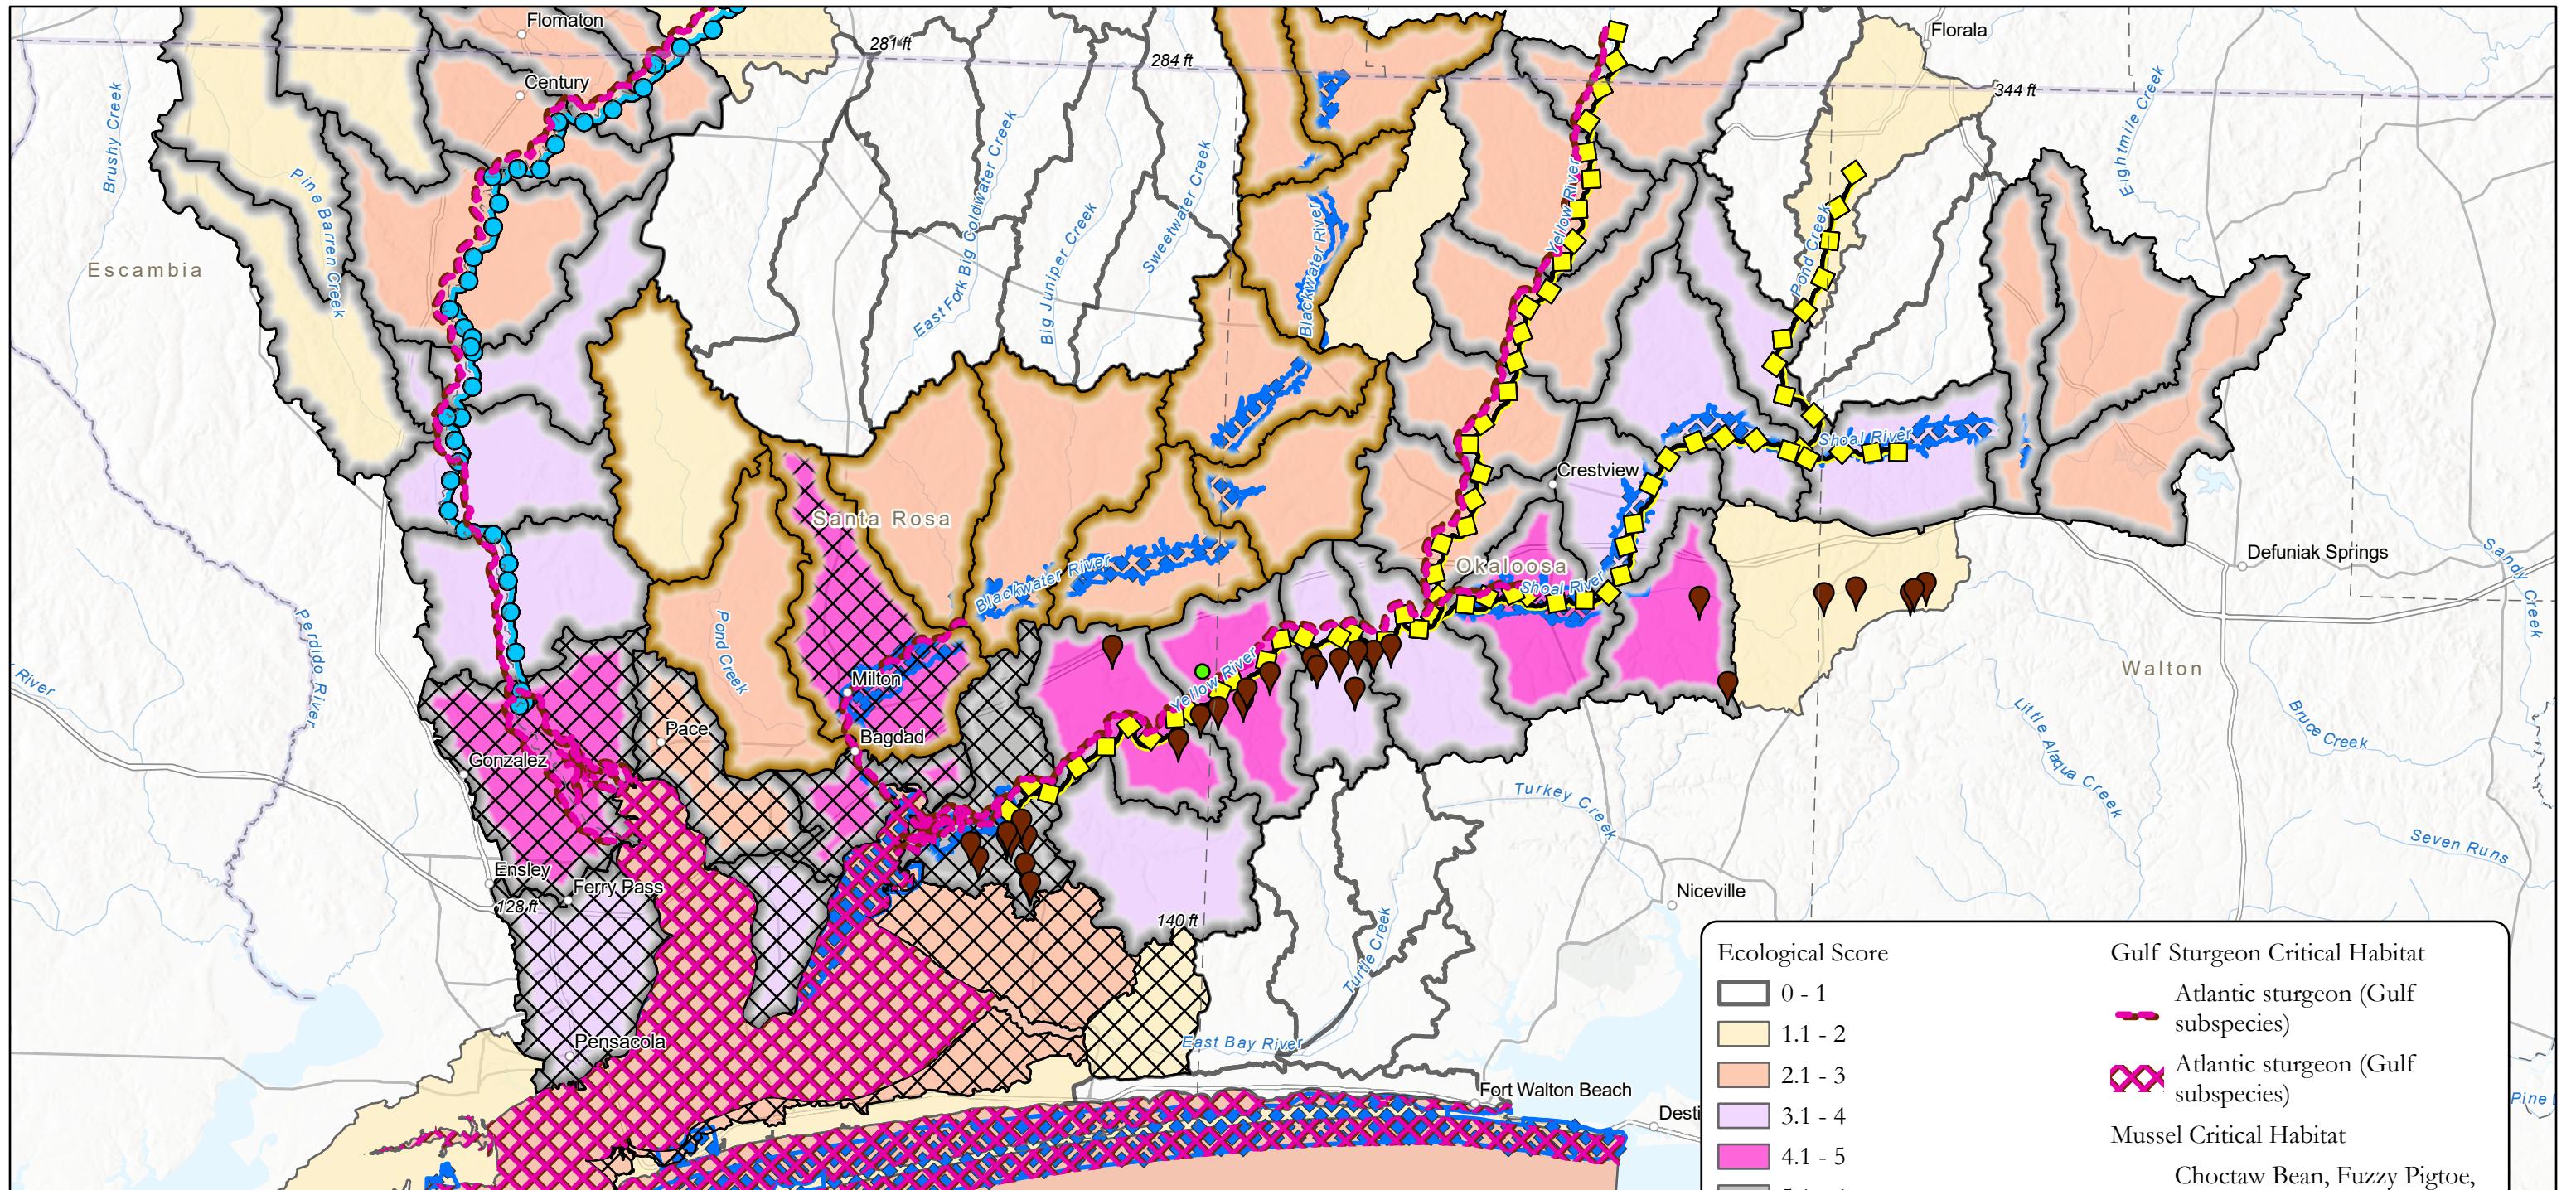

Table 2: Sub-score Ranges

Sub-Score Group	Minimum Possible Sub-Score	Maximum Possible Sub-Score
Outstanding Florida Waters	0.2	2
Species	0	4
Annual Erosion	1	10
Total Possible Points	1.7	16

RESULTS

Annual erosion rates for the 478 road-stream crossings averaged 25.0 tons/yr (or 17.0 tons/yr after multiplying by the delivery fraction and the use-factors). Most sites had annual erosion sub-scores of less than 3; only thirteen sites scored a 9 or above (see Appendix A). When the reduced sediment amounts were summed within their respective 12-digit HUCs, the amount ranged from 0 to 1,245.8 tons/yr (average 190.0 tons/yr). Two 12-digit HUCs where unpaved road-stream crossings contribute the most sediment into Pensacola Bay (both over 1,000 tons/yr) were the Dixon Creek and Upper Big Juniper Creek watersheds in Santa Rosa County. The third highest 12-digit HUC was the Upper Sweetwater Creek (800 tons/yr), located in Santa Rosa County with a small portion in Okaloosa County and in Alabama. Figure 3 depicts the annual erosion estimates from individual unpaved road-stream crossings and from the sum of crossings within each 12-digit HUC.

Species sub-scores ranged from 0 to 4 (Figure 2), and OFW sub-scores ranged from 0.2 to 2 (Figure 1). A map showing both of these scores together is included as Figure 4. When both the species and the OFW scores were combined, there was a pattern where the higher-scored watersheds are those along the Yellow River with gulf sturgeon, bluenose shiner, and mussels. The presence of the Florida bog frog on Eglin Air Force Base along the Yellow River further increased scores along shared watersheds. Some of these locations also drain to OFWs. A higher score indicated a greater need for sediment abatement measures due to the proximity of significant resources or listed species.

Data for 478 unpaved road-stream crossings within the Florida portion of the Pensacola Bay watershed were analyzed according to the methods described above. Total scores ranged from 1.7 (lowest priority for stream crossing restoration/retrofit projects) to 14.7 (highest priority) out of a possible 16 points. The mean score was 5.4 and the median score was 4.8 (see Table 3 and Appendix A).

Table 3: Preliminary Scoring Distributions

Total Score Range	Total Crossings	Percentage of Total
1.7 – 3.9	156	33
4 – 6.9	215	45
7 – 9.9	86	18
10 – 12.9	18	4
13 – 16	3	< 1

Figure 5 shows the locations of the sites and their respective priority scores (grouped and color-coded). Crossings with the highest scores (greater than 13) are located near the Yellow River in Santa Rosa County. Most of the unpaved road-stream crossings that are not programmed for improvements are located in the Blackwater River State Forest and on Eglin Air Force Base.

DISCUSSION

The goal of the project is to improve water quality in Pensacola Bay, specifically through mitigating the effects of sedimentation caused by unpaved roads. To ensure that this remains the focus for prioritizing sites, sediment loading (annual erosion at unpaved road-stream crossings) was weighted more than other elements in the prioritization. These scores were adjusted by sediment delivery fraction and use-factor, such that unpaved road-stream crossings that were further upstream in the watershed or were less traveled were downweighted.

The species and OFW scores were added to the prioritization effort to differentiate close rankings and to ensure that other federal and state concerns (protected waters, state-protected species, etc.) that could benefit from best management practices (BMPs) were considered. The best available data were used for listed species habitats and localities. In this study, an unpaved road-stream crossing received a score for species if it occurred in the same 12-digit HUC as the species. It may be possible to address this limitation by analyzing smaller watersheds.

It is possible to change the weighting of these factors or add additional parameters to emphasize priorities important to project partners or to help differentiate between closely ranked sites. Using slightly different criteria could alter the results of this preliminary prioritization. For example, annual erosion estimates were calculated with an assumed roadway width based on general ownership (county, Eglin AFB, and state forest) and a constant surface type for all roads. JMT will be field assessing 100 ranked sites during execution of Task 6 and will update estimates of annual erosion and associates scores. The field assessment in Task 6 will also be used to calculate Sediment Risk Index (SRI) values for each site, which will provide another factor that can be used to rank unpaved road-stream crossings or to differentiate between closely ranked crossings. The SRI protocol includes twelve metrics involving soil erodibility, roadway slope and approach conditions, roadway sedimentation and drainage abatement features, stream morphology and channel alteration, and overall condition of the structural crossing. Field assessment is necessary as most of these data are not currently available.

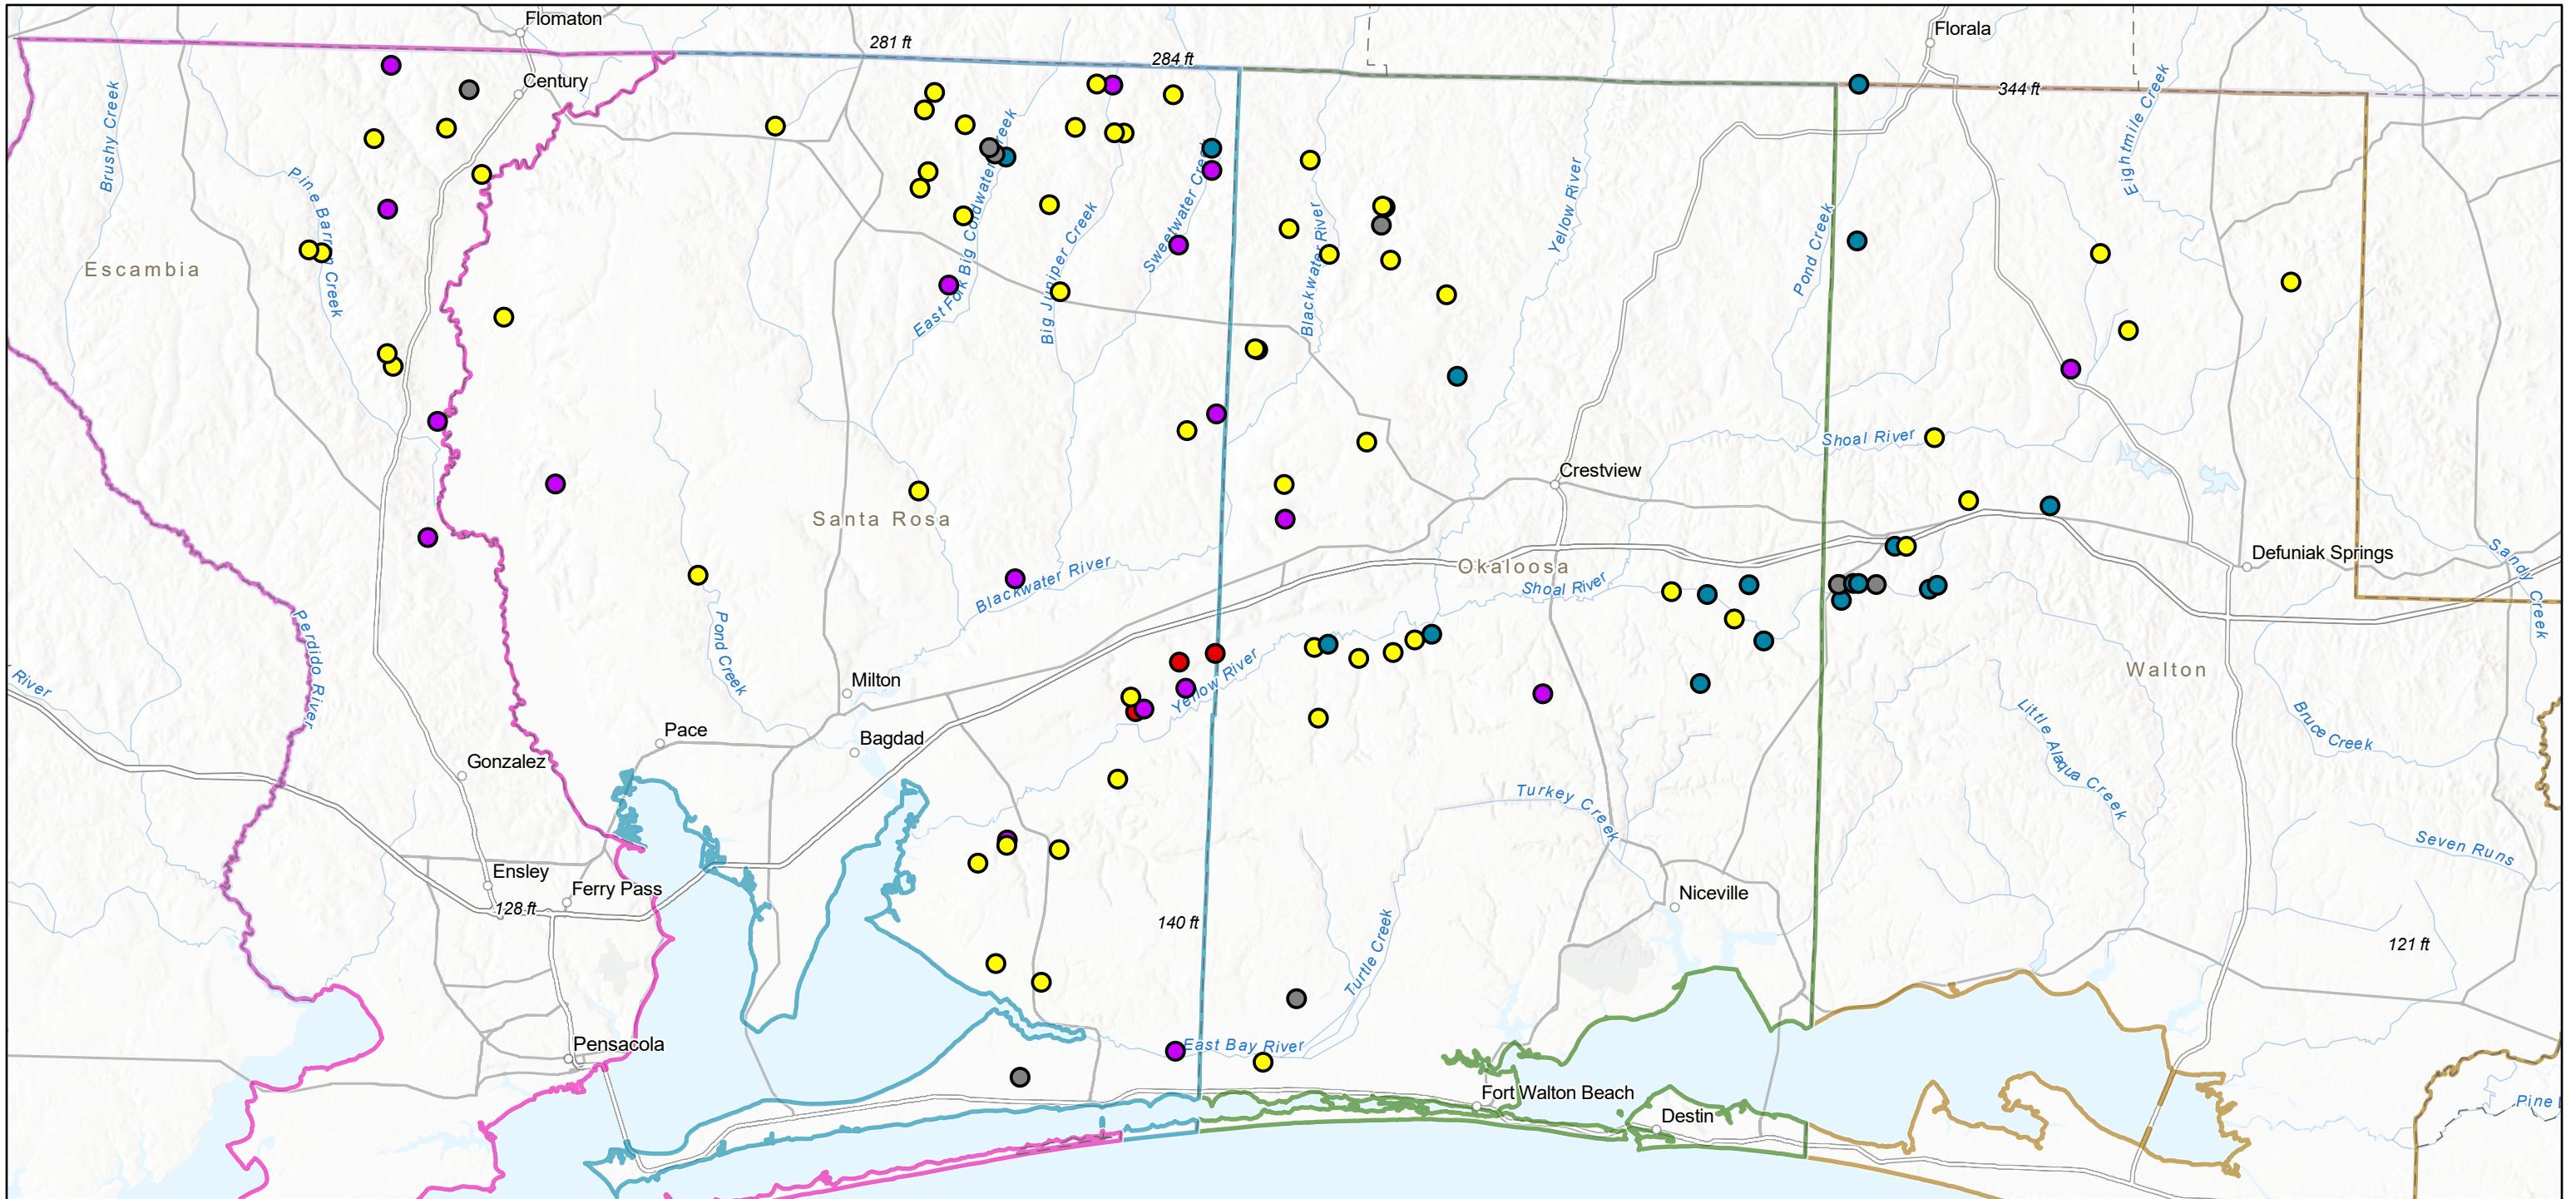

PRELIMINARY PRIORITIZATION LIST

The objective of preliminary prioritization was to rank unpaved road-stream crossings for roadway and drainage improvements that will reduce sediment draining to sensitive habitats. The data provided will help guide such planning. A list of all unpaved road-stream crossings in Florida, sorted by total prioritization score, is included in Appendix A. This list also includes the sub-scores used to calculate the total score. Appendix B lists 47 unpaved road-stream crossings that were identified by project partners as a priority for improvement. Of these, 28 crossings had a prioritization rank lower than 7.0, so they would not have been

included if only the total prioritization score were considered. Because the partner priorities have been field-assessed by the partners, they all have been included in the preliminary list for field assessment. The threshold for the selection of the remaining sites was increased to a score of 8.0. The resulting list includes 105 unpaved road-stream crossings that are not currently programmed for improvement (Appendix C). An overview of this list is depicted in Figure 6. A detailed map book of all unpaved road-stream crossings, with an indication whether a site is a stakeholder priority or a priority determined by JMT, is included in Appendix D.

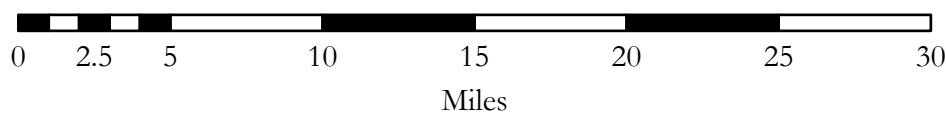

The Pensacola watershed is very large and contains hundreds of unpaved road-stream crossings. Considering groups of sites within the same watershed for improvements may yield more observable and ecologically relevant benefits than by relying solely on the ranking for site selection. Improving widely separated unpaved road-stream crossings may have less measurable benefit given that only fifteen crossings are planned for design and subsequent BMP installation under this project. The approach to site selection may depend on additional field data to be collected during execution of Task 6. Field data from the top 100 crossings and input from project partners will be used to draft the final prioritization list (Task 7).
